

NETBUILDER

How to Launch a Project that has been downloaded from Github.

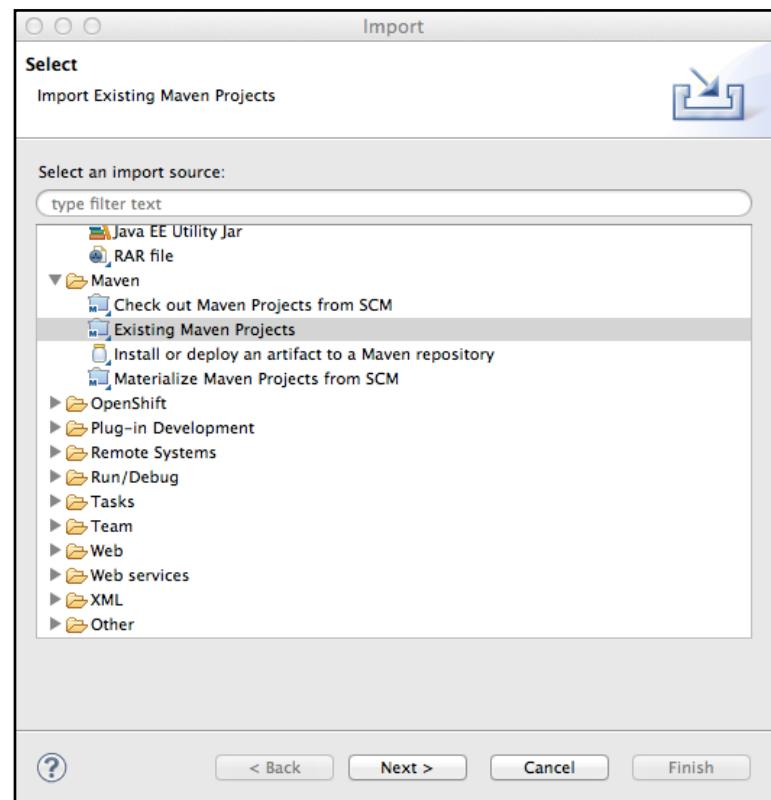

1. Open your Eclipse, then

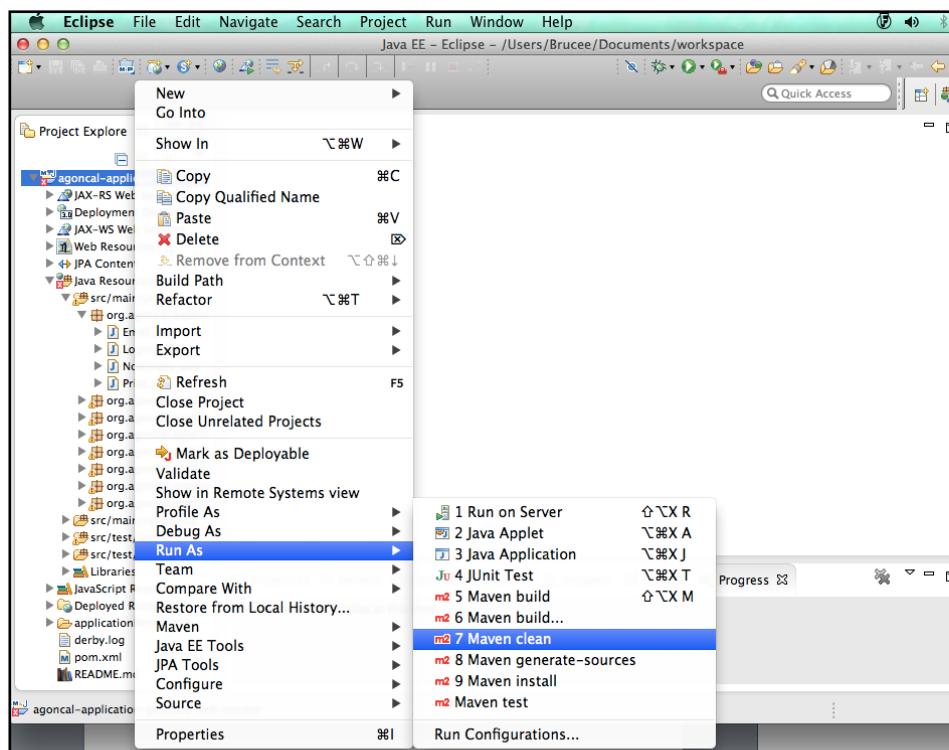

File -> Import-> Existing Maven Projects

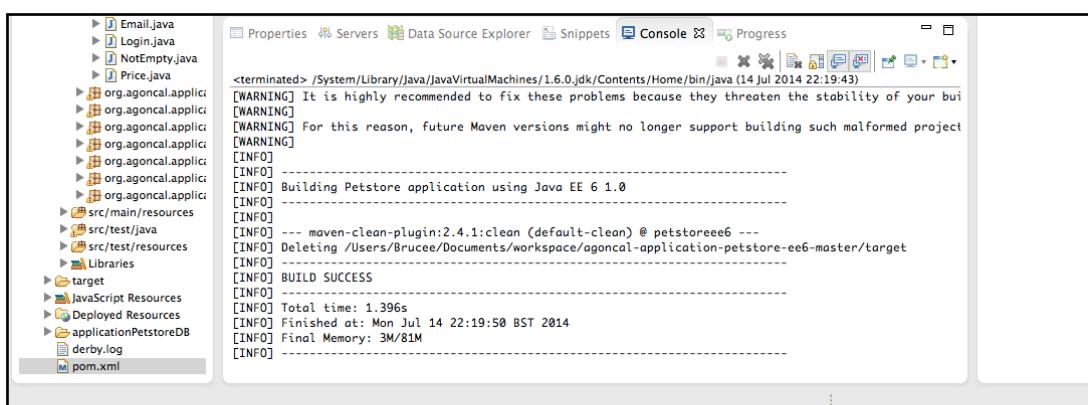

Then select the file path to your Git repository

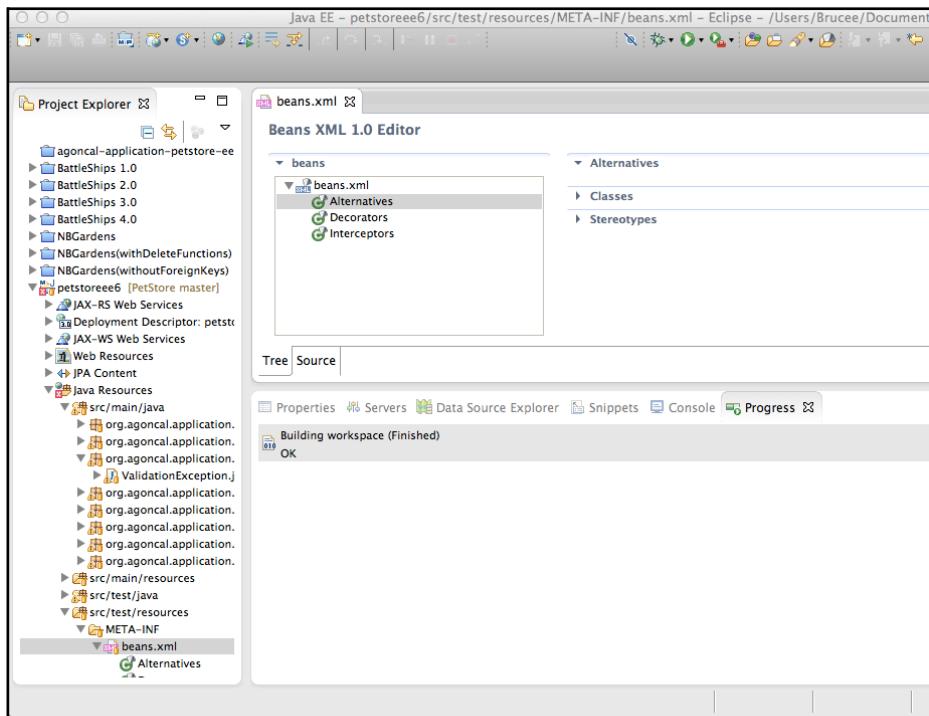

2. Short of doing the maven clean install in your command prompt you can do it by right clicking the project and running it as a maven clean install.

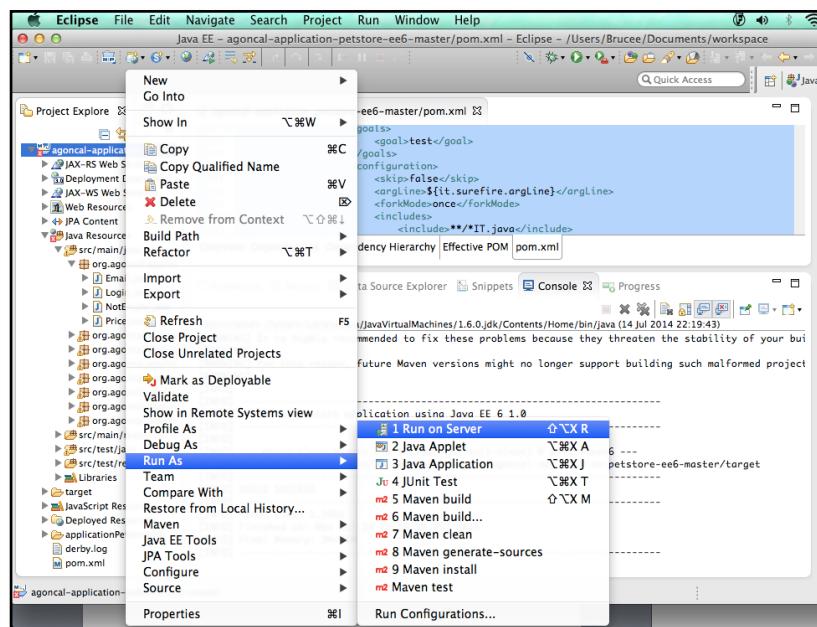

3. You should now have a successful clean maven install.
Yay!!

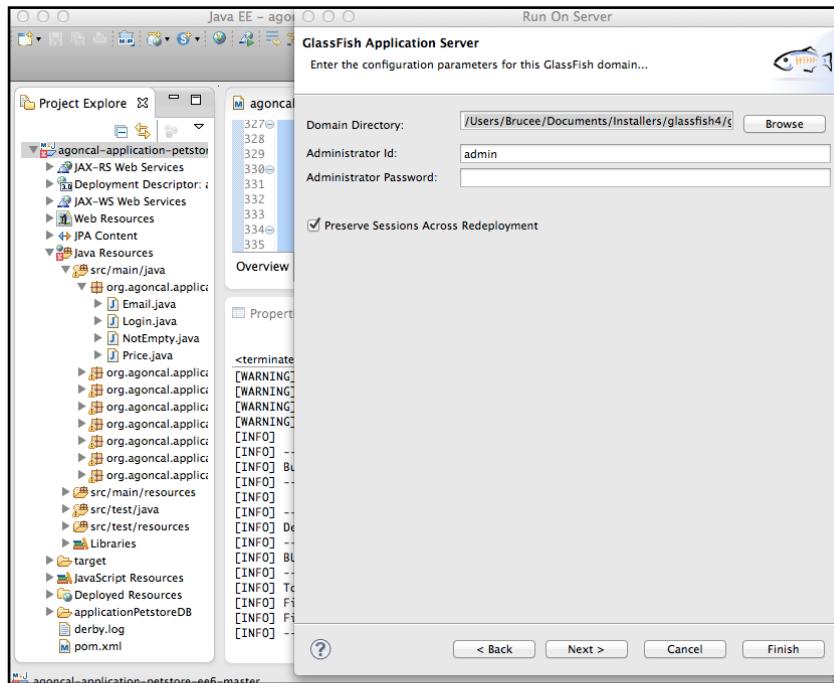

4. Go down to the *beans.xml* file and edit the filepaths to the classes inside your git repository. (Remember to stay classy San Diego)

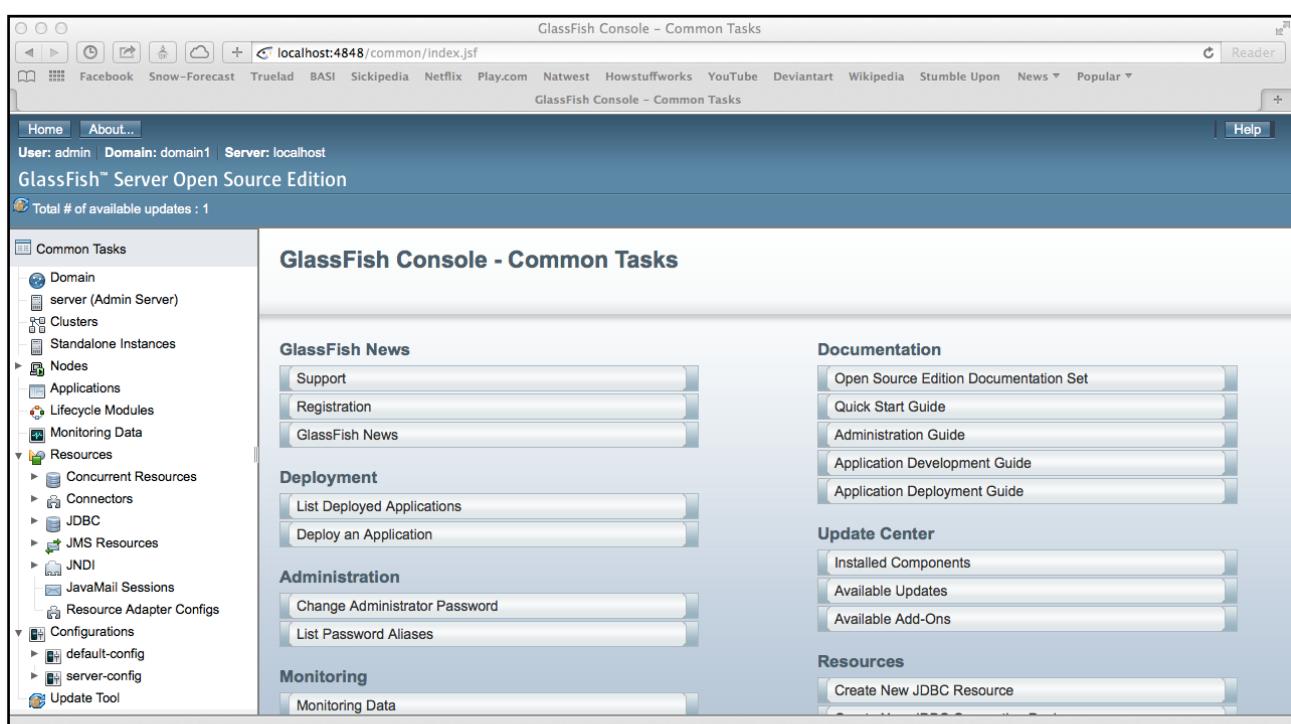

5. After re-maven-ing your project, run on server

5. On the next screen type in the filepath of your Glassfish folder and then *glassfish4/glassfish/domains/domain1*. Add a username and password(don't forget it) and hit finish.

6. The Pet Store has been uploaded to your Glassfish Application server. Pick your favourite browser (safari) and type into the address bar - *localhost:4848*

7. Nearly there, on the left hand side menu select Applications and your project should be there ready to *Launch* and subsequently open in another window.

The screenshot shows the GlassFish Administration Console interface. The title bar reads "localhost:4848/common/index.jsf". The main content area is titled "Applications". On the left, a sidebar menu is visible with the "Applications" item selected. The main panel displays a table titled "Deployed Applications (1)". The table has columns: Select, Name, Deployment Order, Enabled, Engines, and Action. There is one entry: "agoncal-application-petstore-ee6-master" with Deployment Order 100, Enabled checked, Engines ejb, web, and Action buttons for Launch, Redeploy, and Reload.

| Select | Name | Deployment Order | Enabled | Engines | Action |
|--------------------------|---|------------------|-------------------------------------|----------|--|
| <input type="checkbox"/> | agoncal-application-petstore-ee6-master | 100 | <input checked="" type="checkbox"/> | ejb, web | Launch Redeploy Reload |

If this option isn't available, you will have to go back to eclipse and deploy your program as a *WAR* file. (HUH! What is it good for? not absolutely nothing, but finally starting your program in Glassfish Application server).
